CODERSINPUNE HACKATHON / ROUND 2 - THE BUILD

A handover that keeps the why

Baton records decisions and context while work is happening, then gives the incoming engineer a clear path through evidence, open work, ownership, and unresolved risk.

TEAM	PROJECT	ROUND
GIT LOST	Baton	2 / Build

THE PRODUCT IN ONE SENTENCE

Capture during the work. Hand over with context.

Baton is a web workspace for the knowledge that gets lost between engineers: what changed, why it changed, what remains unfinished, who owns the next step, and where project records disagree.

What this build demonstrates

A usable, synthetic handover case with decision capture, claim and source inspection, contradiction review, leaver answers, successor questions, and section-by-section acceptance. The prototype favors traceability and human judgment over pretending that incomplete evidence is certain.

Built with Next.js 14, React 18, TypeScript, and Tailwind CSS. Demo records are fabricated; workflow updates are stored in the current browser profile.

01 / Problem and workflow

The handover gap is a loss of context, not just a missing document.

When an engineer moves on, project history is scattered across pull requests, chat, issues, and personal memory. The successor must reconstruct decisions and chase people for context while trying to identify unfinished work and hidden risks.

Who experiences it

Incoming engineer

Needs a trustworthy map of decisions, open tasks, owners, and uncertainty so they can take over without starting from zero.

Departing engineer

Has context that is not captured in project artifacts and needs a low-friction way to record the why as work happens.

Team lead

Needs to resolve conflicting accounts, route questions, and see what has or has not been accepted.

Product boundary

Baton organizes a transition for one service or project. It does not attempt to replace chat, issue tracking, or source control.

End-to-end workflow

01 **Capture the decision in the moment**

The departing engineer records the change, rationale, next action, and optional reference. The entry is dated, attributed to the selected demo persona, and labeled person-reported.

02 **Review the handover evidence**

The successor scans seeded claims and source excerpts, opens provenance, and sees whether information is confirmed, inferred, missing, or disputed.

03 **Resolve disagreement with a person**

The lead compares contradictory sample records and records a decision or clarification. The product keeps the conflict visible for review.

04 **Fill gaps and ask follow-up questions**

The leaver answers targeted interview prompts. The successor can attach a question to a claim; the lead can record a reply in the same browser.

05 **Accept the handover in sections**

The successor marks reviewed sections, can undo a review, and sees what remains open. This makes acceptance inspectable within the demo.

02 / Product behavior

One workspace connects what was decided, what is still open, and what needs a human answer.

CAPABILITY	WHAT A JUDGE CAN USE	CURRENT BOUNDARY
Decision capture	Save a change, rationale, next action, and optional source reference; review its dated entry.	Browser-local; source references are not validated.
Claim and source ledger	Inspect seeded claims, source excerpts, and provenance; run a deterministic quote-presence check.	Synthetic corpus; a match proves presence, not truth or entailment.
Contradiction review	Compare the sample SQS and RabbitMQ accounts and record a human decision or clarification.	Sample sources only; does not resolve new imported data.
Work and ownership	Review unfinished work, proposed successors, transfer dates, and escalation contacts.	Seeded case; no live issue or owner sync.
Leaver and successor loop	Answer five sample gap questions; ask claim-linked questions; record replies and reversible section review.	Changes remain in this browser; no notifications are sent.
Persona views	Switch successor, leaver, and lead demo views to show reader-specific screens.	A UI simulation, not authentication or access control.

What makes the approach distinct

Uncertainty stays visible

Baton treats disagreement, missing context, and a person's recollection as different states. It does not silently merge competing accounts into one confident answer. Review and resolution remain human actions.

Impact to evaluate

The intended outcome is less successor time spent reconstructing decisions and locating owners. The current prototype has no user study or measured time-saved result. A future pilot should compare time-to-answer a fixed set of handover questions, unresolved issues found, and the number of follow-up contacts needed.

03 / Technical plan and scope

A deliberately narrow build proves the core handover interaction without claiming production infrastructure.

LAYER	IMPLEMENTATION	WHY IT FITS THIS BUILD
Web application	Next.js 14 App Router, React 18, TypeScript	One deployable web app; typed interactions and routes suit a short, iterative build.
Interface	Tailwind CSS and reusable React components	Supports a consistent, responsive workspace and fast refinement of the demo workflow.
Demo state	Client-side store seeded with synthetic case data; localStorage persistence	Keeps the user-facing workflow usable without provisioning a shared database during Round 2.
Quote check	Server route performs deterministic text-presence matching against fixed sample sources	Explainable and reproducible; does not use an LLM or claim logical support.
Hosting	Vercel deployment at gitlostbaton.xyz	A judge can open the live workspace without installing the project.

Major technical challenge: trustworthy claims from messy sources

A source mention can be incomplete, outdated, or in conflict with another record. A text match alone cannot establish that a claim is true. The prototype addresses this by keeping source excerpts and claim statuses visible, distinguishing exact text presence from entailment, and routing contradictions to a human decision. The next technical step is a scoped source import with stable links and explicit handling of stale or unsupported records.

Change from the Round 1 plan

Round 1 proposed PostgreSQL with pgvector and GitHub/project-source integrations. For Round 2, we narrowed scope to a seeded case, browser-local state, a deterministic quote-presence check, and a working human conflict-review path. This keeps the end-to-end handover demonstrable within the event while making it explicit that shared storage, live ingestion, semantic claim checking, and production access control remain future work.

What the prototype does not prove

DATA	IDENTITY	INTEGRATION
Synthetic FinTrack Payment Core records only. Do not enter confidential or operational data.	Persona switching is a demo affordance, not sign-in, authorization, or a security boundary.	No live GitHub, Slack, or Linear connection; no cross-user or cross-device sync.

Development tools: AI assistance was used during development for coding, review, documentation, and a UI concept. The deployed product does not call a generative AI model; its quote check is deterministic.

04 / Delivery plan

A scoped prototype now; the next round should turn local proof into shared, source-linked practice.

Build across the three rounds

ROUND	FOCUS	DELIVERABLE
1 / Plan	Define the handover problem, users, workflow, technical direction, and achievable scope.	Proposal for an accountable engineering handover workspace.
2 / Build	Make the main handover workflow usable end-to-end with a bounded synthetic case.	Public web demo with capture, evidence review, conflict handling, follow-up, and successor acceptance.
3 / Extend	Add meaningful persistence, a real source path, and a traceable shared history.	Three product improvements below, each demonstrable with a testable success criterion.

Three Round 3 improvements

1

Shared, authenticated workspace

Add sign-in, server-side role authorization, and a persistent database. A second user on another device should see the same handover while unauthorized users cannot read it.

2

Scoped GitHub source import

Import selected repositories, pull requests, and commits with stable source links and excerpts. Show import time, errors, unsupported records, and stale-source status.

3

Verified, shared work history

Persist each captured update with author and timestamp, link it to an imported PR or issue, and show source verification separately from the author's explanation. A successor can trace what changed and why across devices.

Team and individual contributions

PARTICIPANT	ROLE	PERSONAL CONTRIBUTION
Aditya Verma	Team leader; full-stack development	Product workflow and application implementation; workspace state, decision capture, review flows, deployment, and Round 2 submission coordination.
Manas Kapoor	Documentation	Document product workflow, technical approach, feature status, and round deliverables; maintain clear proposal and submission materials.
